Car Rental Fleet Manager — Part 1

Module 4: Object-Oriented Modelling, Design & Exception Handling
This part defines the Car class. It provides private fields, a constructor, getters, methods, toString(), and basic exception checks.

Code for this part

```
// Car.java — PART 1 (Module 4)
// Save this file as Car.java

public class Car {
    private String model;
    private int dailyRate;
    private boolean rented;

    public Car(String model, int dailyRate) {
        if (dailyRate <= 0)
            throw new IllegalArgumentException("Rate must be positive");
        this.model = model;
        this.dailyRate = dailyRate;
        rented = false;
    }

    public String getModel() {
        return model;
    }

    public int getDailyRate() {
        return dailyRate;
    }

    public boolean isRented() {
        return rented;
    }

    public void rent() {
        if (rented)
            throw new IllegalStateException("Car already rented");
        rented = true;
    }

    public void returnCar() {
        rented = false;
    }

    public String toString() {
        return model + " - Rs." + dailyRate + "/day - " +
               (rented ? "Rented" : "Available");
    }
}
```

Save as: `Car.java`. This is Part 1 of the same project; use it together with Parts 2 and 3.
